The development and validation of a teacher-reported low-level classroom disruption scale (LLCD-S)
Cogswell, S., Carr, A., Abbott, N. and Monks, C. P.

“This is an Accepted Manuscript of an article published by Taylor & Francis in Emotional and Behavioural Difficulties on 12th September 2020, available online: http://www.tandfonline.com/10.1080/13632752.2020.1816651.”
The Development and Validation of a teacher-reported Low-Level Classroom Disruption Scale (LLCD-S)
Abstract

Low-level classroom disruption (LLCD) is characterised by pupils swinging on chairs, whispering or fidgeting in class. This paper provides initial data on the development and validation of the teacher-rated Low-Level Classroom Disruption Scale (LLCD-S), with two samples of primary pupils. Exploratory factor analysis in Study 1 (N=120) revealed one factor accounting for 61% of the variance; supported by confirmatory factor analysis in Study 2 (N=274), with one factor accounting for 63% of the variance. Both studies reported high Cronbach’s alpha values of .82 and .93. The evidence supports LLCD being a unidimensional construct, measured by the eight item LLCD-S. Weak convergence validity was found between the LLCD-S and the Strengths and Difficulties Questionnaire’s (SDQ, Goodman, 1997) externalising behaviours: conduct problems and hyperactivity. This preliminary evidence indicates that LLCD-S is a valid and reliable measure of low-level classroom disruption. Further research is needed to test the utility of the LLCD-S across different levels of education, cultures and as a pupil-reported measure.

Keywords: low-level classroom disruption scale (LLCD-S); low-level classroom disruption, teacher-report scale; scale validation; primary school.

Word Count: 7264
In a typical primary classroom an individual incident of low-level disruption, such as a pupil calling out or whispering to a peer, may seem like a relatively minor misdemeanour (Clunies-Rosset, Little, & Kienhuis, 2008). In comparison to behaviours characterised as high-level, such as bullying and aggression, the term low-level can imply such behaviours are less impactful on the classroom climate. However, low-level classroom disruption (LLCD) occurs at a high frequency in schools, and teachers consistently identify it as the number one behavioural issue across both primary and secondary schools in England (Bennett, 2017; Elton, 1989; Ofsted, 2014; Steer, 2005). The Office for Standards in Education, Children's Services and Skills (Ofsted) have estimated that LLCD has a negative effect on the education of over 700,000 pupils across the UK with pupils facing “something of a lottery” (Ofsted, 2014, p.5) of being in a classroom where teaching can take place relatively uninterrupted by incidents of LLCD. Bennet, (2017) argues this prevalence rate is underestimated and that LLCD has become a toxic element in the UK classroom. These concerns are reflected in the issue being identified in recent educational policy as a key concern, and a major focus of a national government-funded scheme to support schools in reducing bad behaviour (Department of Education, 2019).

Even though teachers report confidence in handling incidences of LLCD (Ofsted, 2014), they also report greater workplace stress associated with the wearing effect of constant and repetitive interruptions to their teaching (Ofsted, 2014; Scott, Hirn, & Alter, 2014; Wheldall & Merrett, 1988; Wheldall, 1991). Importantly, having responsibilities for wider problems not necessarily within their individual control, such as managing LLCD, is associated with a number of negative outcomes for teachers, namely: emotional exhaustion (Blasé, 1986); lower morale (Maslach, Schaufeli, & Leiter, 2001); maladaptive self-efficacy (Brouwers & Tomic, 2000); losing enthusiasm and idealism for teaching, all factors related to professional burnout (Freudenberger, 1974; Kerr & Valenti, 2009). In their meta-analysis of
classroom management self-efficacy and teacher burnout, Aloe, Amo, and Shanahan, (2014) demonstrated a link across several studies between teachers’ low classroom management self-efficacy and three dimensions of burnout including emotional exhaustion, depersonalisation and lowered personal accomplishment. In line with this, Skaalvik and Skaalvik (2011) found significant correlations between teachers’ perceived negativity towards interruptions caused by LLCD and their feeling of emotional exhaustion.

The impact of LLCD on learning is significant. Emmer, Everston, & Worsham, (2009) suggest that minimal distraction enables effective teaching and learning to take place, with more on-task time correlated with greater learning gains. In contrast, a dysfunctional atmosphere in a classroom can negatively affects pupil attainment and academic success (Haydn, Stephen, Arthur, & Hunt, 2014). Longitudinal research by Duncan and colleagues (2007) found that early disruptions to attention in class at 5-6 years old strongly predicted poor reading and math achievement at 11-12 years old. Importantly, this result controlled for cognitive ability and was similar across gender and socioeconomic status. Furthermore, the relationship between a disruptive classroom environment, poor attainment and lower academic success has been found to extend into early adulthood, with attention problems at primary school predicting lower academic achievements at 17 years, whilst controlling for socioeconomic status and IQ (Breslau et al., 2009).

Although the negative effects of LLCD on teaching and learning are well-documented in educational reports and policy documents, empirical research specifically quantifying and reporting on LLCD is sparse. This noticeable absence of research could be due to the lack of a suitable tool specifically designed to measure LLCD. Elton (1989) highlighted major educational concerns over the accurate recording of LLCD concluding that, “in the absence of national statistics the problem [LLCD] itself could not be directly measured. Any estimate would have to be based mainly on teachers' perceptions” (p.59). More recently, Bennett
(2017) has called for “a national standardised method for capturing data on school behaviour” (p.9) in order to record a range of behaviours including LLCD. The present study sought to address these gaps by designing a standardised scale to specifically measure low-level disruptive behaviours in the classroom. First, it is important to outline the behavioural exemplars that define LLCD, and to differentiate LLCD behaviours from other forms of classroom disruption, named here as high-level behaviours. A delineation of LLCD characteristics now follows.

Swinging on a chair, or fidgeting, can comprise a single act of LLCD which is typically low in intensity or power (Sullivan, Johnson, Owens, & Conway, 2014). LLCD has been described as presenting no physical threat or destruction to others or to school property (Kreisberg, 2017) and being innocuous and/or passive in nature (Beaman & Wheldall, 1997). Conversely, a single act of high-level disruption (e.g. such as a kicking/shouting at a peer or bullying) is of a high intensity and power, typically aggressive, non-compliant and extreme in nature (Wallace, 2017). A single episode of high-level disruption will, as a rule, result in a high enough disturbance for teaching to be suspended, and the perpetrator excluded from the room (Hayden & Dunne, 2001). These behaviours tend to involve only a single child and are relatively infrequent, which can reduce their overall impact on teaching and learning. In contrast, and fundamental to its definition, LLCD occurs at a high frequency, thus effecting classroom functioning more regularly. Although low in intensity, the rate at which incidents of LLCD occur can result in teachers having to implement a range of behaviour management strategies which interrupts and reduces instruction time. Ofsted (2014) reported that 20% of teachers identified interruptions caused by LLCD in every lesson, accounting for up to an hour a day of lost learning time for some pupils. Moreover, due to the high frequency of LLCD and its management being conducted at classroom level, its impact is felt across the
whole class, rather than just a small number of individuals (Hall & Hayden, 2007; Swinson, 2010).

Qualitative accounts from teachers clearly differentiate between the characteristics of LLCD and high-level behaviours, where LLCD is described as persistent, common and an ongoing challenge (Bennett, 2017; Ofsted, 2014; Wallace, 2017). Conversely, Estutgo-Deu and Sala-Roca (2010) found that high-level disruption was reported infrequently and was less concerning for teachers than LLCD. In their study of Spanish primary schools they found that factors associated with LLCD (e.g. unauthorised talking) were the most frequent behavioural problem presented in class (33%), while disruptions of a high-level (e.g. personal confrontations) were least frequent (12%). Similar evidence was found in Australian primary schools ($N = 1380$ teachers), with 50% of teachers stating that LLCD factors occurred several times a day. Whilst 93% of the teachers, reported high-level disruption not occurring at all (Sullivan et al., 2014).

The main characteristics of LLCD are therefore low intensity, passive in nature, high frequency and typically disruptive for the whole classroom. The Ofsted report entitled *Low-level disruption in classrooms: below the radar* (2014) presented behaviours that captured these characteristics as reported by a survey of teachers across primary and secondary schools in England. The *radar* report asked 1,048 teachers to state the most prevalent behaviours that disrupt their classroom. The top three reported were: calling out (over 50% of teachers reported), disturbing other children (almost 50% of the teachers reported) and fidgeting and fiddling with equipment (more than 33% of teachers reported), followed by talking and chatting, not getting on with work, purposely making noise to gain attention, answering back or questioning instructions and, swinging on chairs. The factors identified by teachers in the Ofsted report (2014) were used to underpin the construction and
There are many teacher/carer-rated measures readily available to assess a variety of pupil behaviour. For example, the Children’s Behaviour Questionnaire (Rothbart, Ahadi, Hershey, & Fisher, 2001), assesses temperament (extraversion/surgency, negative affectivity and effortful control), in children aged 3–7 years old. The Sutter-Eyberg Student Behaviour Inventory (Eyberg & Pincus, 1999), assesses both the degree to which a behaviour is problematic and its intensity in children aged 2–16 years. The Strengths and Difficulties Questionnaire (SDQ: Goodman, 1997) is a widely used behavioural screening tool for 3-16 year olds and is often used in clinical settings, measuring positive and problematic behaviour across five sub-scales (emotional problems, peer problems, conduct problems, hyperactivity, and prosocial behaviour). All these measures quantify aspects of childhood behavioural problems. However, none specifically measure behaviours associated with the characteristics of LLCD.

An exception to this is the recently developed Pupil Behaviour Questionnaire (PBQ: Allwood et al., 2018). This is the first scale aimed specifically at quantifying behaviours which are related to LLCD within a community sample ($N = 2074$, age range 4 to 9 years). This teacher-rated scale includes the following items: talking out of turn, interrupting other pupils, making unnecessary noises, making cheeky or rude remarks to the teacher, verbal abuse towards other pupils, and physical aggression towards other pupils. Although these six items achieved Cronbach’s Alpha values of .70 to .90, indicating good to very good internal consistency, the two items relating to verbal abuse and physical aggression are more closely aligned with high-level behaviours and diverge from the characterisation of LLCD identified by teachers (Ofsted, 2014). Furthermore, Allwood and colleagues (2018) compared the scale to the clinically-based Strengths and Difficulties Questionnaire (SDQ: Goodman, 1997) to
assess the construct validity of the PBQ. They found moderate convergence between the PBQ score and the SDQ total difficulties score ($r = .59$). On closer inspection, strong association were evident between the PBQ and conduct problems ($r = .67$) and hyperactivity ($r = .72$) which together indicate externalising behaviour. These moderate to strong convergent associations suggests that both scales may be measuring similar underlying constructs. Moderate divergence was found between the PBQ score and prosocial behaviour ($r = -.53$), suggesting that both scales may be measuring opposing underlying constructs. Weak to no associations were evident between the PBQ and peer problems ($r = .19$) and emotional symptoms ($r = .01$) which indicate internalising behaviour. These results suggest a strong association between externalising behaviours and LLCD as measured by the PBQ. This diverges from a definition of LLCD as presenting no physical threat or destruction to other pupils or to school property (Kreisberg, 2017), and as being more passive in nature (Beaman & Wheldall, 1997). Although Allwood and colleagues (2018) concluded that the similarities with the SDQ represented good construct validity of the PBQ, we argue this is does not support the notion of LLCD as being distinct in nature and impact from high-level disruptions, in which are behaviours more closely associated with conduct problems and hyperactivity (Bennett, 2017; Ofsted, 2014; Sullivan et al., 2014; Wallace, 2017) and that the PBQ may not be a reliable measure of LLCD.

The Present Research

The present paper aimed to report on the construction and validation of a scale to quantify levels of teacher-reported LLCD in primary schools. Eight items taken directly from the Ofsted report (2014), which specifically reported on LLCD, were used to construct this new LLCD-S. These were (Q1) calling out, (Q2) disturbing other children, (Q3) fidgeting and fiddling with equipment, (Q4) talking and chatting, (Q5) not getting on with work, (Q6) purposely making noise to gain attention, (Q7) answering back or questioning instructions
and, (Q8) swinging on chairs. As with exploratory analyses no priori hypothesis relating to these factors and patterns was predicted.

Construct analysis was also carried out. Convergent validity was assessed, correlating the LLCD-S total score with the SDQ total difficulties score and the sub-scales of externalising behaviour. We predicted weak to moderate associations with the LLCD-S, indicating convergent validity. Divergent validity was assessed comparing the LLCD-S total score with the SDQ sub-scale score of prosocial behaviour. In keeping with the view that LLCD is not overtly associated with anti-social behaviour (Kreisberg, 2017), a moderate negative correlation was predicted. Additional comparisons were carried out between the LLCD-S score and the SDQ sub-scales of internalising behaviour. No direct associations were predicted between LLCD and internalising behaviour.

Given that the initial analysis of the LLCD-S was limited to the construction sample (Study 1) it was vital to test whether the scale properties would remain the same when applied to another sample. For Study 2, a cross-validation of the proposed unidimensional LLCD-S was investigated, including internal reliability and one-dimensionality, with an independent sample of primary age pupils ($N=274$). It was hypothesised that LLCD as measured by the 8 item LLCD-S is a one-dimensional construct.

**Method**

**Participants**

Four of the five participating schools were recruited via existing contacts of the main researcher. The fifth school was recruited via a letter drop to primary schools within a 25-mile radius of the main researcher’s base in the county of Kent, UK. Both the schools for
Study 1 (referred to as School 1 and School 2) and two of the schools in Study 2 (referred to as School L and School M) were located in the same urban area. The third school for Study 2 (referred to as School G) was located in a rural area, in the county of Cambridgeshire, UK. All five schools, were mixed gender and similar in cohort size (between 348 to 412 pupils) Ofsted inspections reported the schools as; school 1 ‘required improvement’ (2015) and school 2 ‘satisfactory’ (2012), School G ‘good’ (2014), School M ‘good’ (2015). No Ofsted data was available at that time for School L. Table 1 details the Office of National Statistics (2016) data, highlighting the characteristics of the areas the schools were drawn from and the national figures.

[Insert Table 1 here]

The sample selection was determined by age. Adolescence (12 years +) can be regarded as a turbulent period in the behavioural trajectory of childhood (Steinberg, 2005; Youniss & Smollar, 1985). The onset of puberty has been associated with hormonal changes that can influence behaviour (Steinberg, 2005), sometimes generating behaviour problems not previously presented (Harms, Zayas, Meltzoff, & Carlson, 2014). Therefore, it was advantageous to recruit a pre-adolescent sample, in order to limit such behavioural disturbances.

To allow for familiarity to have formed between the class teacher and their pupils, all data for both studies were collected during the final academic summer term. Study 1 took place across two primary schools located in the county of Kent, UK. LLCD data was collected from the class teachers (N=4) reporting on the pupil sample (N=120). The pupils self-reported their year group, age and gender. The pupil sample was spread across two year groups (5 and 6) with an age range of 9-11 years old ($M_{age} = 10.29, \ SD = .64$). Of the total
pupil sample, 49.2% were in year 5 and 50.8% were in year 6. 59% of pupils identified as male, 41% identified as female. Study 2 took place across three primary schools located in the counties of Kent and Cambridgeshire, UK. Using the LLCD-S, data was collected from the teachers ($N=8$) reporting on the pupil sample ($N=248$). The pupils self-reported their year group, age and gender. The pupil sample was spread across two year groups (year 4 and 5) with an age range of 8-10 years ($M_{age}=9.34$, $SD=.66$). Of the total pupil sample, 47.8% were in year 4 and 52.2% were in year 5. 49% of pupils identified as male, 51% identified as female.

**Measures**

**Low-level classroom disruption.** The intent of this scale construction was to generate items to measure low-level classroom disruption specifically. Past literature has defined LLCD as having the characteristics of low intensity, high frequency and as having impact across the classroom as a whole unit (Halsted & Xiao, 2009; Kreisberg, 2017; Sullivan et al., 2014; Swinson, 2010). To reflect this definition, and to ensure a sufficient breadth of LLCD content was included, the eight highest teacher-rated behavioural issues as highlighted in the Ofsted report (2014) were selected as items. For the present study, teachers were instructed to rate how often each individual pupil in their class carried out the following acts: calling out, disturbing other children, fidgeting and fiddling with equipment, talking and chatting, not getting on with work, purposely making noise to gain attention, answering back or questioning instructions and swinging on chairs. Responses were rated on a three-point scale of 1 (never), 2 (sometimes), 3 (a lot), with a higher score indicating a higher presentation of LLCD. Following guidance of prior scale development work (Clark & Watson, 1995), all eight items were positively worded to avoid ambiguity in the interpretation of meaning. Limiting the scale to eight items also enables the teachers to complete quick assessment on every child in the class (Slade, Thornicroft, & Glover, 1999).
Cronbach’s alphas values were very good to excellent, with Study 1 equal to .82 and Study 2 equal to .93.

**Behaviour.** For Study 1, teachers also completed The Strengths and Difficulties Questionnaire (SDQ: Goodman, 1997) for each pupil. The SDQ is a well-validated behavioural screening questionnaire for 3-16 year olds, typically completed for clinical diagnostic purposes. The SDQ measures emotional and behavioural changes. Consisting of five subscales (emotional symptoms, peer problems, conduct problems, hyperactivity, and pro-social behaviour), there are 25 items rated on a three-point Likert scale (Not True, Somewhat True and Certainly True). A total difficulties score is derived by summing emotional symptoms, peer problems, conduct problems and hyperactivity. Regarded as difficulties, a higher score on the total SDQ (or on the subscales of emotional symptoms, peer problems, conduct problems and hyperactivity), indicates higher difficulty in establishing adaptive behaviour. Regarded as a strength, for pro-social behaviour the reverse is true, with a higher score indicating a higher level of this adaptive behaviour. An externalising behaviour score can be created by summing hyperactivity and conduct problems, and an internalising behaviour score can be created by summing emotional symptoms and peer problem scores. The SDQ has a test-retest correlation of .85 (Goodman & Scott, 1999) displaying strong evidence of construct validity. See Table 2 for the present study Cronbach’s alpha values for the SDQ totals and subscale.

| Insert Table 2 here |

**Procedure**

For both studies, the head teachers granted consent for the research to take place. Each school distributed information letters regarding the study to the pupils’ parents/guardians, with the option to withdraw their child/s from the study. There were
minimal opt-out requests returned to the schools, Study 1=3, and Study 2=14. The class teachers (Study 1 N=4, Study 2 N=8) received information regarding the purpose of the study and informed that any data collected would be confidential in nature and anonymised. All the teachers approached granted their consent to participate. For Study 1, teachers received the Low-Level Classroom Disruption Scale (LLCD-S) and the Strengths and Difficulties Questionnaire (Goodman, 1997). For Study 2, teachers received the Low-Level Classroom Disruption Scale (LLCD-S). For both studies, teachers received a master list of pupils’ names and pupils’ personal codes (Study 1 N=120, Study 2 N=274). Teachers completed the questionnaires in their own time, recording each pupil’s personal code along with a personal code of their own. On completion of the data collection, all participants (parents, pupils and teachers) received debriefing forms. These contained full details of the study, ethical issues such as post hoc withdrawal from the study and information about help/support lines should they require this.

**Results: Study 1**

**Descriptive statistics**

On average, pupils in the sample were 10.29 years old (SD = .64; range 9-11) at the time of the data collection. The sample was made up of 59 boys and 61 girls (N=120). Table 3 presents the means, standard deviations and bivariate correlations of the LLCD-S items from Study 1. All items of the LLCD-S were positively correlated and larger than .3.

[Insert Table 3 here]

**Exploratory Factor Analysis (EFA)**

EFA assessed the eight items of the teacher-rated LLCD-S with maximum likelihood estimator, using SPSS (IBM). The sample size and the strength of relationship between the items indicated suitability of the data for EFA. With a Kaiser-Meyer-Olkin value for the data
set of .8, being greater than the recommended .5 (Kaiser, 1970). The strength of the relationship between the items considered Pearson’s correlations and revealed the presence of all coefficients larger than .3. Bartlett’s test of sphericity (Bartlett, 1954) tested the overall multivariate correlations within the correlation matrix and was significant ($\chi^2(28) = 542.64, p<.001$). Thus, indicating normality of distribution, supporting the factorability of the data (Table 3). Following the eigenvalue rule, stating only eigenvalues larger than one retained (Howitt & Cramer, 2017), the EFA analysis identified the existence of one factor. With an eigenvalue equal to 4.88 achieving a total variance in the data of 60.92%. As Table 4 indicates, the component matrixes revealed very strong loadings on this one factor for all eight items of the measure (> .50).

[Insert Table 4 here]

Inspection of the scree plot revealed a clear elbow with one point above this, supporting a one-factor solution (Figure 1). Parallel Analysis further supported these results, which showed only one component with eigenvalues exceeding the corresponding criterion values for a randomly generated data matrix of the same size (8 variables x 120 respondents). These results demonstrate that all eight items converge on the same factor, indicating one salient construct underling the LLCD-S item scores. Rotation did not take place, as all eight items loaded sufficiently onto one factor. The LLCD-S demonstrated excellent internal consistency with a Cronbach’s alpha value of .82. This result compared very favourably with the recommended value for scales used in research of above .6 (Nunnally, 1978).

[Insert Figure 1 here]

**Convergent Validity**

Convergent validity was investigated by calculating Spearman’s correlation coefficients between the LLCD-S and the scale, and sub-scales of the SDQ (Goodman, 1997).
As was predicted small positive correlations were found between the LLCD-S score and the SDQ total difficulties and the hyperactivity sub-scale scores, indicating weak similarities. These similarity was noticeably weaker than the moderate similarities that were found for these convergent correlations by Allwood and colleagues (2018). Contrary to the prediction, a medium positive correlation was found between the LLCD-S total score and the conduct problems score, as measured by the SDQ sub-scale. This correlation was similar to the correlation found between LLCD, as measured by the PBQ, and conduct problems as measured by the SDQ sub-scale during previous research (Allwood et al., 2018). As was predicted convergent investigations carried out between the LLCD-S score and the SDQ externalising behaviour scale score found a medium correlation, indicating a moderate similarity (Table 5).

**Divergent Validity**

To assess divergent validity Spearman’s correlation coefficients were computed. In keeping with the prediction a medium negative correlation was found between the LLCD-S total score and the SDQ prosocial behaviour sub-scale score. This correlation value was similar to that previously reported between the PBQ and the SDQ prosocial behaviour sub-scale during previous research (Allwood et al., 2018). Contrary to the prediction stating that no association would be found, a significant correlation was found between the LLCD-S score and the SDQ sub-scale score of peer problems, however this was a weak association. Once again this was similar to the correlation found by previous research (Allwood et al. 2019) between the PBQ and the SDQ sub-scale of peer problems. As was predicted, no significant associations were found between the LLCD-S and the SDQ total internalising behaviour sub-scale or the sub-scale of emotional symptoms (Table 5).

[Insert Table 5 here]
Results: Study 2

Descriptive Statistics

On average, pupils in the sample were 9.34 years old (SD = .66; range 8-10) at the time of the data collection. The sample was made up of 121 boys and 127 girls ($N = 248$). Table 6 presents the means, standard deviations and bivariate correlations of the LLCD-S items from Study 2. All correlation coefficients between the items of the LLCD-S were greater than .3.

[Insert Table 6 here]

Confirmatory Factor Analysis

Considering the one-factor solution identified in Study 1, confirmatory factor analysis was conducted to test the following hypothesis: Low-level classroom disruption, as measured by the eight item LLCD-S, is a one-dimensional construct. Replicating the model from Study 1, the CFA model for the teacher-reported LLCD-S constrained all eight items to load onto one factor. Model fit assessed the CFA indices, indicating a good fit: $X^2(272) = 174.33$, $p<.001$, SRMR=.052, CFI=.90 and TLI=.86 (Hu & Bentler, 1999). Moreover, all standardized factor loadings were statistically significant, ranging from .64 to .88 (Table 7). Overall, CFA results indicate adequate factor structure for the cross-validation sample. Reflecting Study 1, the Cronbach’s reliability coefficients for Study 2 recorded an alpha value of .93 indicting excellent internal consistency.

[Insert Table 7 here]

Discussion

These studies describe the construction and factor structure of the teacher-reported Low-Level Classroom Disruption Scale (LLCD-S), providing preliminary evidence of the reliability and validity of one factor. First, the study presented previous literature and
outlined differences between the concept of low-level classroom disruption and high-level classroom behaviours. LLCD has been consistently defined by teachers as being of low intensity, passive in nature, high frequency and typically disruptive for the whole classroom (Bennett, 2017; Ofsted, 2014; Wallace, 2017). Whereas, high-level classroom behaviours are conversely characterised by their high intensity, low frequency and typically disruptive for only the perpetrator of the maladaptive behaviour (Bennett, 2017; Ofsted, 2014; Sullivan et al., 2014; Wallace, 2017). Based on this differential and evidence reported in the Low-level disruption in classrooms: below the radar report (Ofsted, 2014), which specifically investigated LLCD, the eight items capturing the behaviour exemplars of LLCD were defined as: (Q1) fidgeting or fiddling with equipment, (Q2) purposely making noise to gain attention, (Q3) swinging on chair, (Q4) disturbing other children, (Q5) not getting on with work, (Q6) answering back or questioning instructions, (Q7) calling out, and (Q8) talking and chatting. These eight behaviour exemplars were included as the items for the development of the LLCD-S.

Due to the exploratory nature of this new scale no priori hypothesis was forecast. The Study 1 values for the KMO and the Bartlett’s sphericity test revealed that the sample of 120 was large enough for exploratory factor analysis (EFA) to take place and that scores were normally distributed. EFA yielded a one-factor structure, with all eight items loading significantly onto this one factor, explaining 61% of the total variance. As for any scale development it is imperative that the internal consistency of the scale properties is tested on additional data sets. Therefore, Study 2, evaluated the LLCD-S with a new sample of 274 primary pupils. The hypothesis that low-level classroom disruption as measured by the eight item LLCD-S is a one-dimensional construct was upheld. Confirmatory factor analysis (CFA) based on the previous EFA results from Study 1, supported a single factor model and explained 63% of the total variance. Estimates of the internal consistency of a scale should
range from .7 to .9 to indicate reliability (McCrae, Kurtz, Yamagata, & Terracciano, 2011). Encouragingly, the single factor scale showed strong internal consistency for both Study 1 and Study 2 (.82 and .93 respectively), indicating that all eight items were measuring the same underlying concept of LLCD and that the LLCD-S is a highly reliable scale across two different samples of primary aged pupils. These excellent internal consistency results allow for the preliminary conclusion that the LLCD-S is an accurate measure of the presentation of low-level classroom disruption with a primary school sample. It therefore provides education practitioners with a much needed and long awaited means of systematically capturing LLCD (Bennett, 2017; Elton, 1989).

Adding strength to the development of this new measure, Study 1 assessed the construct validity of the LLCD-S by concurrently collecting teacher-rated scores from the SDQ (Goodman, 1997). As expected, results show strong divergent validity between the LLCD-S and prosocial behaviour as measured by the SDQ; moderate convergent validity between LLCD-S and externalising behaviour, and weak convergent validity with internalising behaviour. The LLCD-S was designed to capture low-level behaviours in classroom settings while the SDQ was designed to capture higher level behaviours in clinical populations, and therefore while we expected some convergence, the two scales are measuring distinct underlying constructs. In comparison, the convergence between externalising and the LLCD-S noticeably lower in strength than convergence with the Pupil Behaviour Scale (Allwood et al., 2018).

Crucially, LLCD has been consistently highlighted as the number one behavioural issue in primary schools across the UK; causing more ongoing concerns than high-level behaviours (Bennett, 2017; Estutgo-Deu & Sala-Roca, 2010; Ofsted, 2014; Wallace, 2017). It is therefore imperative that when measuring behaviour in the classroom only behaviours specifically conducive to low-level disruption are captured. The timing of this present report
is of added importance in light of the English Government’s recent announcement that in September 2020 a programme of research will be launched to tackle bad behaviour in the classroom, specifically including investigations of LLCD (Department of Education, 2019). The LLCD-S could provide an evidenced-base too with which to measure LLCD and evaluate interventions.

A major strength of this report is the replication of the scale reliability over two studies. Despite this, there are some limitations to consider. First, the present study aimed to limit the capturing of behavioural disturbances associated with adolescence, therefore both samples were restricted to pre-adolescent primary pupils aged between 8-11 years. However, this limits the generalisability of the results. As LLCD is reported as a significant issue at secondary education too it is highly recommended that future research should look to expand the sample age range to include adolescence and/or post-adolescence. This would enable important investigations to observe the influences on, and the changes to LLCD during and across key developmental stages. Second, the research locations were limited to the counties of Kent and Cambridgeshire, UK. In order to capture a more diverse sample, including diverse socio-economic factors future investigations of LLCD should look to widen the research areas and include school samples from across the UK, and beyond. Third, this paper only reports on the observer-rated scores of the LLCD-S from class teachers. Future studies could evaluate a pupils’ self-reported LLCD-S in order to reduce the risk of common method variance. Finally, the cross-sectional nature of this study does not allow for test-retest assessment of the external reliability of the LLCD-S. Having the same sample report levels of LLCD, over two or more separate data collection waves, would allow correlations between the time points to be calculated. Therefore, future studies could overcome this limitation by implementing a longitudinal design.
Concluding Remarks

In conclusion, LLCD has been consistently emphasised as the number one behavioural issue in primary schools, having negative impacts on both the teachers and the pupils (Bennett, 2017; Elton, 1989; Ofsted, 2014; Steer, 2005). Considering this, and addressing a recognised gap in the literature, the LLCD-S can be effectively utilised for screening and/or as an outcome measure recording an accurate account of low-level classroom disruption presentation at primary school level (Elton, 1989; Ofsted, 2014). Importantly, the LLCD-S focuses specifically on LLCD clearly addressing only low-level maladaptive behaviours, differentiating from measures that include high-level maladaptive behaviours. This scale would be beneficial to quantify levels of LLCD across individual pupils, classrooms and schools. Further exploration of the scale is required across time with various age populations, and additionally as a pupil self-report measure.

**Appendix**

*The Low-level classroom disruption scale (LLCD-S)*
This is a chance to find out about the pupils’ behaviour in your classroom. Please write your own personal code and each pupil’s individual code in the spaces below. Be sure that your answers show accurately how each individual pupil behaves. Please read each item then place a tick in the box to indicate the individual pupil’s level of presentation for each behaviour. Please do not talk to anyone about your answers. We will keep your answers private and not show them to anyone.

</tbody>
</table>

Scoring the LLCD-S. Each item is scored as 1-Never, 2-Sometimes, 3-Often. The scores are summed with a possible range of 8 – 24. A higher score indicates a higher presentation of LLCD.
